#### **Outline**

- Pointer Basic
- Pointer Arithmetic
- Function Pointers
- String Basic
- String Functions
- Q&A

### sizeof operator

- Returns size of operand in bytes (at compile-time)
- For arrays, sizeof returns
  - ( size of an element ) \* ( number of elements )
     int myArray[ 10 ];
     cout << sizeof( myArray );</pre>

### sizeof operator Cont'd

- Can be used with
  - Variable names
  - Type names
  - Constant values
- Parentheses are only required if the operand is a type name

#### Pointer Arithmetic

- Increment/decrement pointer (++ or --)
- Add/subtract an integer to/from a pointer (+ or +=, or -=)
- Pointers may be subtracted from each other
- Pointer arithmetic is meaningless unless performed on a pointer to an array

- 5-element int array on a machine using 4-byte int vPtr = &v[0];
  - vPtr points to first element v[ 0 ], at location 3000
     vPtr += 2;
  - sets vPtr to 3008 (3000 + 2 \* 4)
  - vPtr points to v[2]
- Subtracting pointers
  - Returns number of elements between two addresses vPtr2 = &v[2]; vPtr = &v[0]; vPtr2 - vPtr?

- Pointer can be assigned to another pointer if both are of same type
  - If not, use cast operator
  - Pointer to void (void \*)
    - Generic pointer, represents any type
    - No casting needed to convert pointer to void \*
    - Casting is needed to convert void \* to any other type
    - void pointers cannot be dereferenced

- Pointer comparison
  - Use equality and relational operators
  - Compare addresses stored in pointers
    - Comparisons are meaningless unless pointers point to members of the same array
  - When checking whether pointer is 0 (null pointer)
- Arrays and pointers are closely related
  - Array name is like constant pointer
  - Pointers can do array subscripting operations

```
int b[] = \{ 10, 20, 30, 40 \}; int b[] = \{ 10, 20, 30, 40 \};
int *bPtr = b;
                              int *bPtr = b;
for (int i = 0; i < 4; i++) for (int i = 0; i < 4; i++)
   cout << "b[" << i << "]=";
                                 cout << "b[" << i << "]=";
   cout << b[ i ] << endl; cout << b[ i ] << endl;
for ( int f1 = 0; f1 < 4;
                          for ( int f1 = 0; f1 < 4;
   f1++ )
                                  f1++ )
   cout << "*(b+" << f1;
                                 cout << "*(b+" << f1;
   cout << ")=";
                                cout << ")=";
   cout << *(b+f1) << endl;
                               cout << *(b+f1) << endl;
```

### **Arrays of Pointers**

```
const char *a[ 4 ] =
    { "Hearts", "Diamonds", "Clubs", "Spades" };
```

- Each element of a points to a char \* (string)
- Array a has fixed size (4), but strings can be of any size
- Commonly used with command-line arguments to function main

#### Pointers to Functions

- Contain addresses of functions
  - Function name is starting address of code that defines function
- Passed to functions
- Returned from functions
- Stored in arrays
- Assigned to other function pointers

# Calling Functions using Pointers

- Function header bool (\*foo) (int, int)
- Execute function from pointer with either
   (\*foo)(x, y)
  - Dereference pointer to function, or foo(x, y)
  - Use the pointer directly
    - Could be confusing

#### **Function Pointers**

```
void selectionSort( int [],    int a[ aSize ] =
                                     { 2, 6, 4, 8, 10,
   const int,
                                      12, 89, 68, 45, 37 };
  bool (*)(int, int));
void swap( int * const,
   int * const );
                                cin >> order;
                                if ( order == 1 ) {
bool ascending( int, int );
                                   selectionSort(a, aSize,
bool descending( int, int );
                                               ascending);
int main()
                               else
   const int aSize = 10;
                                   selectionSort(a, aSize,
   int order;
                                              descending );
   int counter;
```

#### **Function Pointers Cont'd**

```
void selectionSort( int w[], const int size, bool
    (*compare)(int, int))
  int smallestOrLargest;
  for ( int i=0;
        i<size - 1; i++ )</pre>
      sorl = i;
      for ( int idx = i + 1;
             idx < size;</pre>
             idx++)
        if( !(*compare)
            ( w[sorl], work[idx] ) )
             sorl = idx;
      swap(&work[sorl], &work[i]);
```

#### Function Pointers Cont'd

```
void swap( int * const element1Ptr, int * const element2Ptr )
{
   int hold = *element1Ptr;
   *element1Ptr = *element2Ptr;
   *element2Ptr = hold;
bool ascending( int a, int b )
   return a < b;
}
bool descending( int a, int b )
   return a > b;
```

### Arrays of Pointers to Functions

- Menu-driven systems
  - Pointers to each function stored in array of pointers to functions
    - All functions must have same return type and same parameter types
  - Menu choice determines subscript into array of function pointers

## Character Constant and String

- Integer value represented as character in single quotes
  - 'z' is integer value of z
    - 122 in ASCII
  - '\n' is integer value of newline
    - 10 in ASCII
- String
  - Series of characters treated as single unit
  - String literal (string constants)
    - "I like C++"
    - Static storage class
  - Array of characters, ends with null character '\0'
  - String is constant pointer to string's first character

# String Assignment

Character array

```
char color[] = "blue";
char color[] = { 'b', 'l', 'u', 'e', '\0' };
```

- Creates 5 element char array color
- Last element is '\0'
- Variable of type char \*
   char \*colorPtr = "blue";
  - Creates pointer colorPtr to letter b in string "blue"
  - "blue" resides somewhere in memory

# Reading Strings

- Assign input to character array word[ 20 ]
   cin >> word;
  - Reads characters until whitespace or EOF
  - Reads only up to 19 characters (space reserved for '\0')
- String could exceed array size cin >> setw(20) >> word;

### cin.getline

- Read line of text cin.getline( array, size, delimiter );
  - Copies input into specified array until either
    - One less than size is reached
    - Delimiter character is input

```
char sentence[ 80 ];
cin.getline( sentence, 80, '\n' );
```

### <cstring> Library

- Manipulate string data
- Compare strings
- Search strings for characters and other strings
- Tokenize strings (separate strings into logical pieces)
- Data type size\_t
  - An unsigned integral type
    - Such as unsigned int or unsigned long
  - Defined in header file <cstring>

# String Functions

- char \*strcpy( char \*s1, const char \*s2 )
  - Copies second argument into first argument
    - First argument must be large enough to store string and terminating null character
- char \*strncpy( char \*s1, const char \*s2, size\_t n )
  - Specifies number of characters to be copied from second argument into first argument
    - Does not necessarily copy terminating null character
- char \*strcat( char \*s1, const char \*s2 )
  - Appends second argument to first argument
    - First character of second argument replaces null character terminating first argument
    - You must ensure first argument large enough to store concatenated result and null character
- char \*strncat( char \*s1, const char \*s2, size\_t n )
  - Appends specified number of characters from second argument to first argument
    - Appends terminating null character to result
- size\_t strlen( const char \*s )
  - Returns number of characters in string

# String Functions Cont'd

- int strcmp( const char \*s1, const char \*s2 )
  - Compares character by character
  - Returns
    - Zero if strings are equal
    - Negative value if first string is less than second string
    - Positive value if first string is greater than second string
- int strncmp( const char \*s1, const char \*s2, size\_t n )
  - Compares up to specified number of characters
    - Stops if it reaches null character in one of arguments
- Character codes / character sets
  - Machine dependent
  - ASCII
    - "American Standard Code for Information Interchage"
  - EBCDIC
    - "Extended Binary Coded Decimal Interchange Code"
  - Unicode

## **Tokenizing**

- Breaking strings into tokens
  - Tokens: logical units, such as words (separated by spaces)
  - Separated by delimiting characters
  - "This is my string"
    - 4 word tokens (separated by spaces)
- char \*strtok( char \*s1, const char \*s2 )
  - Multiple calls required
    - First call contains two arguments, string to be tokenized and string containing delimiting characters
      - Finds next delimiting character and replaces with null character
    - Subsequent calls continue tokenizing
      - Call with first argument NULL
      - Stores pointer to remaining string in a static variable
  - Returns pointer to current token

### String Example

```
#include <cstring> // prototype for strtok
using std::strtok;
int main()
   char sentence[] = "This is a sentence with 7 tokens";
   char *tokenPtr:
   tokenPtr = strtok( sentence, " " );
   while ( tokenPtr != NULL )
      cout << tokenPtr << '\n';</pre>
      tokenPtr = strtok( NULL, " " );
   cout << "\nAfter strtok, sentence = " << sentence</pre>
   << endl;
   return 0;
```
